Mitral Valve Obstruction and Pulmonary Hypertension Caused by a Giant Left Atrial Myxoma Prolapsing in the Left Ventricle

Abstract

Atrial myxomas are the most common primary cardiac tumors to diagnose. They are benign and have variable presentation. They have an excellent prognosis following surgical excision. We report a case of a 60 year old female who presented with initial signs of both right and left heart failure, fever and cough. Auscultation of the heart revealed an apical mid diastolic murmur. Trans-thoracic and trans-esophageal echocardiography revealed a pedunculated, giant left atrial myxoma that prolapsed through the mitral valve into the left ventricle in diastole producing functional mitral valve stenosis. The patient underwent a successful surgical excision of the tumor. The diagnosis and management of atrial myxomas is here reviewed.

Discussion and Conclusions

Metastases (most commonly from the lung, breast, melanoma, lymphomas and leukemias) are responsible for the majority of cardiac...
tumors [2-4]. Primary tumors are relatively rare in the heart and most of them are are benign. Myxomas are the most common accounting for about 50% of all primary tumors and 75% of all benign tumors. Atrial myxoma is a tumor of the heart that occurs primarily in the LA [1]. The clinical signs and symptoms may be aspecific. The size of the tumor differs widely among patients but generally ranges from 2 to 6 cm. Depending on the size and location, it may cause mitral valve functional obstruction and pulmonary hypertension. Seventy five percent of mixomas are found in the LA and most present between the third and sixth decade of life, with 75% of patients being female. Similar to ours, all patients in reported surgical series [5-7] were symptomatic and presented with one or more triad of constitutional, embolic or obstructive manifestations.

In reviewing some of the largest surgical series, Lukacs et al. [5], over a 20 year period operated on 50 myxomas, with 42 (84%) in the LA, and operative mortality of 10% primarily from low cardiac output syndrome. Hanson et al. [6] with a 24 year review of 33 patients with atrial myxomas reported 3% mortality from tumor emboli to the coronary circulation. Similarly, Cleveland et al. [7] 15 years review of 20 patients with cardiac tumors reported 10% mortality. There was a preponderance of females in the three series but there was no racial breakdown.

Myxomas are easily diagnosed by echocardiogram, with transesophageal echocardiogram (TEE) nearly 100% sensitive. Without echocardiogram they can be misdiagnosed as mitral valve disease, dilated cardio-myopathy, pulmonary emboli, transient ischaemic attack or cerebro-vascular accident [7]. In conclusion, the treatment of choice for myxomas is surgical removal, and this is usually curative. After the diagnosis has been established, surgery should be performed in a short time frame because of the possibility of embolic complications or sudden death [8]. The prognosis is excellent with reported surgical mortality rates ranging from 3% to 7-10% [9].
