Keywords: Music intervention; Cancer; Emotion (anxiety/depression); Randomized controlled trial

Introduction

Emotional distress in cancer patients happens during their acute treatment and after treatment ends [1,2]. Some cancer patients were reported to have positive results after treatment. However, many patients suffered severe traumatic stress and showed regressive, withdrawn and angry behaviors [3-6]. Non-pharmaceutical interventions play an important role in alleviating these symptoms, including pain, depression, anxiety, and poor quality of life during the treatment of cancer [7-9]. Among these complimentary interventions, music intervention attracted a lot of attention from both patients and clinicians for fewer side effects and being cost effective [10-12]. This review summarizes evidences supporting effects of music intervention from clinical trials, and presents challenges and opportunities for further research and studies in this emerging area.

Methods

Design

This study is a literature review about music interventions to manage emotion changes in cancer patients. The current studies with different designs will be synthesized to address the issue. Thus, the inclusive articles should follow the following inclusion criteria and exclusion criteria.

1. Inclusion Criteria
   Full articles published from 1991 to 2015 in English and Chinese.
2. Trials used a RCT design and tested a music intervention.
3. Sample studies were human subjects of any age.

Exclusion Criteria

1. Studies were excluded if the intervention test was not included in the classification of music-based intervention.

Search strategy

The PICOS strategy, namely Population (P), Intervention (I), Comparison (C), Outcome (O) and Study design (S), was applied for a systematic search of the published articles. In our study, we established P (population) for cancer patients; I (intervention) for music-based intervention; C for comparison of music intervention with another type of intervention or untreated group; O for management of emotion changes and disease progress; S for exception of cross-sectional studies and surveys studies [13,14].

Review process

The author read the included studies one by one independently and summarized the aim of this review in Table 1: (1) author, (2) sample size, (3) gender, (4) cancer type, (5) main findings. The information was abstracted and filled in the Table by consensus.

Results

Initially, 277 articles were collected and 88 articles among them were included according to the inclusion and exclusion criteria. The titles and abstracts were then read one by one. 10 articles were selected for the final review and delivered on one occasion [15-24]. Most of the studies (90%) reported significantly emotion improvement after music treatment compared with the control group. Only one study (10%), however, reported no significance between the two groups. The effects of music intervention mentioned in the included studies were analyzed in detail as follows (Figure 1).

Discussion

Our review aims to summarize and analyze evidence based proof of effectiveness of music intervention on the management of emotional stress in cancer patients. As presented in the results of included studies, well-structured, trained and organized music intervention showed better effects on the quality of life and emotion...
improvement in cancer patients. However, there is no clear clinical practice guidelines used in the clinical study [25-28]. Thus, standard is recommended for the intervention quality control, in which the researchers can reduce the dropout rate reported in previous studies [29,30].

The included 10 studies were all random assignments and specified eligible criteria. Only one study reported double blind trial, namely blind subjects and blind therapists. Thus, the placebo effects could not be ignored in the majority of studies. The interventions applied in the studies varied in content, duration, and dose. Most interventions were individualized according to the needs of subjects and therapists.

Through this review, despite having limited investigations in this field, we found that a much stricter methodology should be highlighted and paid attention to [31]. In addition, diverse methodologies were found in the studies which affected the heterogeneity of meta-analysis and review article [32-34]. For example, the present review article could hardly make a conclusion on the effects of music-based intervention due to different cancer types, genders, and measurement tools.

**Perspective**

Specifically, more conceptual and mechanisms studies of this field are needed. To get an optimal intervention for cancer populations, it is urgent for the researchers to obtain identification of methodological components because inconsistencies would block the development of music therapy. Different results from various studies, which might contribute to various cancer types, different cancer stages, various treatments, and different intervention durations, should be explored for the psychological beneficial of cancer patients in the future investigations. Additionally, theoretical framework, which can provide rationale for the intervention of cancer patients, should also be highlighted and paid attention to. Homogenous populations, including cancer types and cancer stages, and intervention durations, should be considered for the future clinical translation.
