Localized Myxedema on the Upper Eyelids in a Patient of Hypothyroidism

Letter to Editor

Localized myxedema may be observed in hypo/hyperthyroidism [1]. However, the affected sites are usually pretibial area and the lesion on the eye lid is rare. We report a case of myxedema on the bilateral upper eyelids, which was a diagnostic clue of hypothyroidism associated with Hashimoto disease.

A 42-year-old Japanese woman presented with upper eyelid swelling of 2 months duration (Figure 1a). She did not complain muscle weakness or myalgia. She showed no dry coarse skin, tremors of the hands, thick tongue, or loss of hair. Histopathology of the skin biopsy revealed swelling of the collagen bundles with splitted individual fibers accompanied with pale material (Figure 1b), which was stained with blue with colloidal iron (Figure 1c). Laboratory investigation revealed decreased free T4 (0.88 ng/ml (1-1.8)), decreased free T3 (1.12 pg/ml (2.73-4.5)), and increased TSH (10.34 IU/ml (0.27-4.29). Anti-thyroid, anti-microsome, anti-thyrogloblin and anti-thyroid peroxidase antibodies were positive. Total cholesterol (286 mg/dl) and triglyceride (342 mg/dl) were elevated. Other laboratory findings including anti-nuclear antibody, aldolase, creatine kinase, and angiotensin-converting enzyme showed normal results. Echo examination disclosed slight but diffuse swelling of thyroid gland. Chest X-rays showed no abnormality and no malignant disease was detected in CT. The patient was diagnosed as localized myxedema with hypothyroidism due to Hashimoto disease. After three months of thyroid hormone replacement therapy, the skin lesions gradually improved accompanied with euthyroid state. We got the informed consent form the patient.

Localized myxedema may be observed in hypothyroidism [1]. However, the reports of the eyelid myxedema in hypothyroidism are few and Ohtsuka et al., reported myxedema on the skin including both eyelids in hypothyroidism [3]. Our case is the second of localized myxedema with lesions restricted on the upper eyelids. Clinical differential diagnosis may include dermatomyositis, which was negated by laboratory findings of normal muscle enzyme activity, no increase in anti-nuclear antibody, and no liquefaction degeneration of basal cell layer of epidermis in histopathology.

We report a case of myxedema on the upper eyelids, which may be a clue of diagnosis of hypothyroidism.
