Abstract

When it comes to application of specific material properties, high accuracy and minimal rework of nano-metal components are the key elements for a successful process. The parts can be either produced by Laser melting, or by metal injection moulding, depending on the volumes of the desired applications.

These nanostructured materials are possible to produce on different material basis, however titanium is preferred. Both options are usable for medical parts. The technology is defined by the numbers of pieces which need to be produced.

Introduction

It is for good that the number of powder metallurgically produced parts continues to grow. The benefits are obvious, since the parts are produced in this way correspond very closely to the final geometry: They are characterised by very high accuracy as well as surface quality.

Development is processing to such a point that the quality of such parts may be higher than that of precision cast parts – but only if the manufacturing process is mastered.

Laser melting or Metal Injection Moulding

When looking at 2 technologies, it is necessary to understand how the technology works and where the issues are. For Laser melting, the technology is melting the steel powder directly to the desired 3-d-geometry. For this technology, a laser melting machine is necessary [1]. The geometry of the 3-d-printed part is cut into horizontal “slices” and they are lasered layer by layer in the building area of the machine [2,3].

For Metal Injection Moulding, the approach is completely different with the same final material, but a completely different process: Here the mix out of polymer and metal powder is injected into the injection moulding machine. Then the part is demoulded fully automatically [4].

And then, the material is injected part is post treated by debinding and sintering process. In this regard, the mould, the injection moulding machine, the laser melting machine and experience represent the key factors that preserve special attention in order to evaluate the question what technology to use (Table 1).

Figure 1: Comparison Laser Melting and Metal Injection Moulding

Figure 1 shows what technology can be used depending on the requirements of the desired parts. Apart from the volume, it is always also a question how big the parts are. Generally spoken Metal Injection Moulding is only applicable for high

volumes and fairly small parts up to a part weight of 50 g (recommended) and maximum weight of 150 g [4].

**Laser melting as an option for small volumes**

In this regard, the mould, the injection moulding machine, the laser melting machine and experience represent the key factors that preserve special attention.

Picture 1 shows a part which is produced via laser melting. Here, the Core of an injection mould for a nasal douche part is produced. The unique of this laser melted part is the integrated cooling of the system. The different parts on the photo show the different production cycles of the material. Here, it is necessary to consider the exact machine parameters [1], the correct design releaseases of the material [2] as well as the adequate machining strategy [3].

Production of parts via powder metallurgy has been practised for some time. For instance, powder metallurgy has been used for decades to produce friction bearings with properties that satisfy precisely the application requirements such as the essential one of operation under emergency running conditions, among others. These benefits, however, can be realised economically only with moderate to large production quantities. For smaller volumes, laser melting is the best choice in order to produce medical devices [4].

For higher volumes, the combination of sintering with the relatively inexpensive process of injection moulding, which leads to injection moulding of metal powder represents one approach to achieving this objective. Almost all alloys that are available in powder form can be employed for this process. Standard steels, stainless alloys, as well as magnetic steel powder can all be processed via injection moulding [5].

When looking at the pros and cons of this technology, the following pros and cons (Figure 2) can be considered.

**Special know how for MIM for higher volume**

Successful implementation of the MIM process requires special know-how, especially with regard to the injection moulding machine and the mould. When injection moulding, it has been found that electronically controlled machines can be controlled more precisely via the controls than can their hydraulic counterparts [4].

Attention must be also given to the screw geometry in conjunction with the injection nozzle. No special measures are required for protection against wear, nitried screws and barrels are satisfactory. For long production runs, hardened screws are recommended — as with the conventional injection moulding.

Selection of the injection mould is more difficult, since the part geometry and planned annual production volume must be taken into consideration along with the possibilities offered by the injection moulding machine.

When looking at this sample, it becomes evident that the selection of the gate location and a good cooling of the mould-system is the decisive criterion for success [5]. Based on the function of the part, the designer establishes where the gate, parting lines and ejector can be located. Her must have an idea of the mould filling behaviour for various approaches to gating and specify the most favorable one [6]. The detailed design concludes the work and should take all consideration into account.

When looking at the pros and cons of this technology, the following pros and cons (Figure 3) can be considered.

**Outlook**

Additional examples of the successful use of Nano-structured Laser melted parts are other mold devices such as areas where the cooling of the system is very important. As far as MIM-parts is concerned, other parts for Titanium applications can be used easily as MIM parts. The great advantage of MIM ist...
that the materials can be processed via injection moulding and the material properties of both the plastic and metal can be tailored to the applications. The importance of metal injection moulding and also Laser melting of nanostructured parts will grow especially in the fields that require a combination of plastic injection moulding and the metalforming to meet demanding requirments. The author thanks the Federal Ministry of Education and Science for the donation in the project Kitkadd for Lasermelted applications [7].
